Review

• benzene, C_6H_6 , stable & unreactive

• explained by

1.) resonance (*last lecture*)

2.) MO Theory

good starting point:

"MO's are formed by combination of similar AO's; similar in *energy, size, shape*"

recall: # of MO's = # of "originating" AO's

applied to benzene:

p AO's → π MO's

6 p AO's → 6 π MO's

Illustration:

"6 p AO's combine in various ways to form 6 π MO's"

(*in-phase, out-of-phase, varying # of nodes ...*)

Nodes in MO's

(areas w/ zero e^- density)

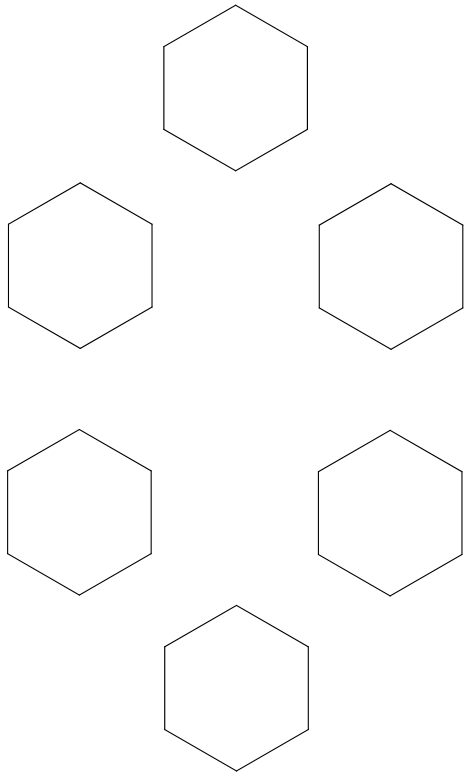
rule: "as # of nodes increases, the energy of the MO ↑ "

(*b/c less binding, it is easier for the molecule to fall apart*)

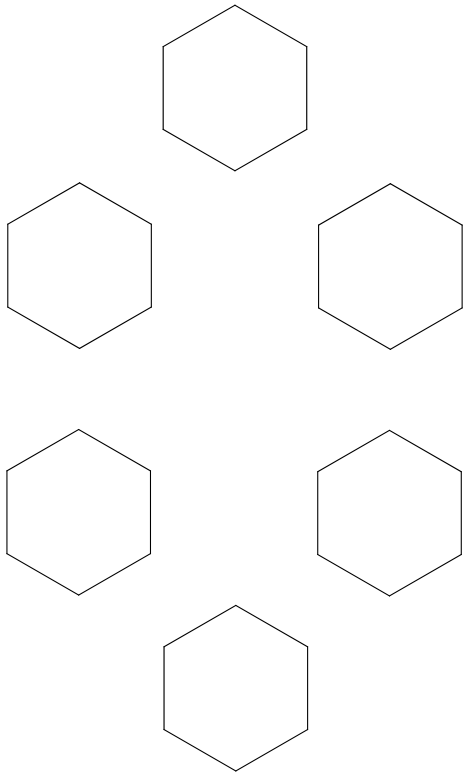
MO Energy Diagram

comment: *the # of MO's at lvl 2 & 3 doubles up because of symmetry considerations*

Originating/Contributing p AO's



Resulting MO's



Occupation of MO's by e^-'s

In the ground state of the benzene molecule:

all e^-'s are in lower energy orbitals ("bonding"),
none in higher energy orbitals ("anti-bonding)",
when compared with the originating p AO's

$\therefore$ reason for **aromatic stabilization**

(*similar MO arguments apply to all other aromatic systems*)

Hückel's Rule

predicts aromaticity of org. cmpds.
(*containg rings w/ high level of unsaturation*)

A. **Aromatic**, if

1.) monocyclic system

(*rule can be extended to polycyclic systems, such as naphthalene)*

2.) ring planar

3.) each atom in ring can be sp^2 hybridised;
p AO's form π sytem ("sideways overlap")

4.) π sytem contains

B. **Anti-Aromatic** (unstable), if

1.)
2.) } same as in A.
3.)

C. **Non-Aromatic** (behave "normally")

all others;

esp., non-planar systems

Examples

A.) Aromatic

1.) n = 1, 6 e^-'s

2.) n = 4, 4n + 2 = 16 + 2 = 18 e^-'s

B.) Anti-aromatic (*very unstable*)

C.) Non-aromatic

looks anti-aromatic: 8 e^-'s, n = 2 , "4n rule";

but behaves like normal alkene;

conclusion: system must be non-planar,

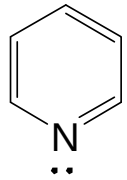
approx. "tub-like":

Variety of Aromatic Structures

- can contain heteroatoms (N, O S, ...)
- may be ionic

Examples:

Pyridine



N is sp^2 hybridised;

has 3 sp^2 orbitals and 1 "pure" p orbital:

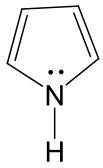
- p orbital involved in aromaticity
- 2 sp^2 orbitals form σ bonds w/ C atoms
- 1 sp^2 orbital contains lone pair of e^-'s

∴ lone pair not used in aromaticy

"remains exposed"

remains quite basic

Pyrrole



N is sp^2 hybridised;

has 3 sp^2 orbitals and 1 "pure" p orbital:

sp^2 orbitals form 3 σ bonds;

p orbital (w/ 2 e^-'s)

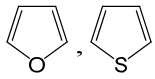
contributes to aromatic system

∴ lone pair "used up" in aromaticy

"not exposed"

pyrrole much weaker base than pyridine

similar arguments for furan, thiophen (HMWK)



Anions

Ex. cyclopentadienyl anion, $C_5^-H_5^-$

(forms easily from cyclopentadiene with bases such as OH^-)

planar, monocyclic system,
all C's sp^2 hybridised,
conjugated π system
6 e^-'s (Hückel #)

aromatic

Cations

Ex.1.: cylopropenyl cation, $C_3H_3^+$

(suitable Lewis acid, trityl cation: $Ph_3C^+ BF_4^-$)

aromatic requirements satisfied:

planar, monocyclic system,
all C's sp^2 hybridised,
conjugated π system
2 e^-'s (Hückel #)

aromatic

Ex.2.: cyloheptatrienyl cation, $C_7H_7^+$

aromatic requirements satisfied, as before !

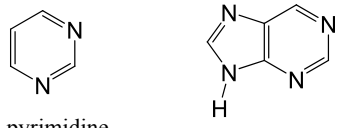
Cycloheptatriene **Cycloheptatrienyl cation**

FIGURE 14.12 The stylized *p* orbitals of cycloheptatriene and of the cycloheptatrienyl (tropylium) cation.

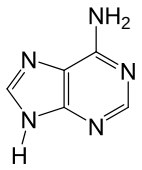
Complex Heterocyclic Aromatics

important in Biochemistry

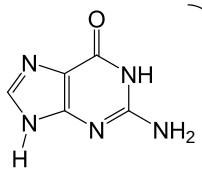


pyrimidine

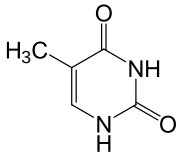
purine



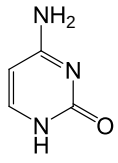
adenine



guanine



thymine



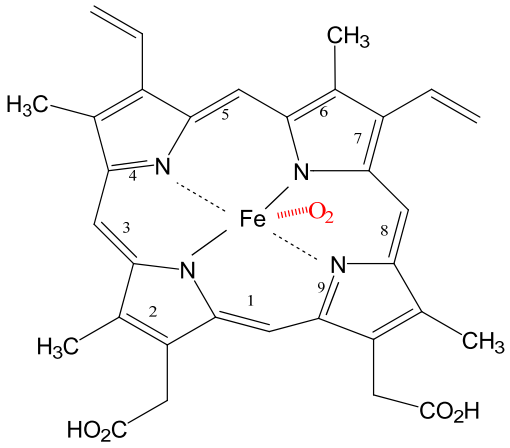
cytosine

DNA Bases

Another Aromatic System

of biological importance

Heme, part of hemoglobin,
oxygen carrier in red blood cells



numbers indicate double bonds that are part of aromatic system

n = 4, 4n + 2 =18; 18 e⁻'s = aromatic

Spectroscopy

1.) NMR

a.) δ (*aromatic*) ~ 7.0 ppm

HMWK:

do similar calc^{ns} for 60 and 500 MHz instruments.

b.) J values

ortho = 9 Hz

meta = 2 Hz

para ~ 0.5 Hz (negligible)

c.) effect of substituents

2.) IR

"aromatic bond"	type	wavenumber
= C – H	stretch	~ 3030 cm^{-1}
C = C	stretch	1600 – 1650 cm^{-1}
= C – H	bend	900 – 700 cm^{-1}
