

Energetics of Forming Bondsex)  $\text{H}_2$ Linear Combination of Atomic Orbitals (LCAO)

- Gives molecular orbitals (MO)
- Overlap of s atomic orbitals (AO)  $\rightarrow$  gives sigma( $\sigma$ ) MO (cylindrical symmetry)
- Difference between AO and MO  $\rightarrow$  AO present on an atom while MO present between two atoms when bond is formed.
- In terms of strength  $\rightarrow$   $\sigma$  bond is stronger than a  $\pi$  bond. But a double bond is stronger than a single bond because double bonds contain two bonds ( $\sigma$ -bond +  $\pi$ -bond).

## Methane, CH<sub>4</sub>:

- tetrahedral geometry
- for any 2 bonds electron density is equidistant from nucleus
- four covalent bond between the carbon atom and the hydrogen atoms
- the angle between two H-atoms = 109°

## Hybridization:

- mixing of atomic orbitals (with wrong geometry for bonding) to form the hybrid orbitals that have correct geometry for bonding

Figure: Hybridization of 2<sup>nd</sup> shell s orbitals (one) and p orbitals (three) of carbon

- the 2s orbital and 2p orbitals of carbon are mixed (hybridized) to form the four degenerate (equal energy) sp<sup>3</sup> orbitals
- note: sp<sup>3</sup> comes from the fact that one s-orbital and three p-orbitals are mixed
- once the hybrid orbitals are formed, four hydrogen atoms can share the four electrons of the outer (bonding) shell of carbon to form four covalent bonds
- now, carbon is isoelectronic to neon and hydrogen is isoelectronic to helium

## sp<sup>3</sup> hybridization

- Tetrahedral geometry
- Single bonds
- Bond angles of 109°

### sp<sup>2</sup> hybridization

- 3 atoms connected to carbon.
- Mixing of the one 2s and two out of the three 2p orbitals. One p-orbital left over.
- Planar geometry
- Usually double bonds
- Bond angles of 120°

Ex) ethylene, ethene

- When atomic orbitals overlap they form molecular orbitals.
- Double bond contains one  $\sigma$  bond and one  $\pi$  bond.
- $\pi$  bond fixes geometry, does not allow rotation along double bond.
- $\sigma$  bond has free rotation.

### sp hybridization

- Two atoms bonded to central atom
- Linear geometry
- Usually triple bonds
- Bond angle is  $180^\circ$

ex) Acetylene

- Hybridization occurs in order to optimize geometry and decrease non-bonded interactions between atoms having inert gas configuration.

## Molecular Size and Shape

- H-Y Y= C, O, N, bond length are  $\sim 1 \text{ \AA} = 10^{-8} \text{ cm}$
- X-Y X, Y= C, N, or O bond length are  $\sim 1.5 \text{ \AA}$
- X=Y X, Y= C, N, or O bond length are  $\sim 1.35 \text{ \AA}$
- $X \equiv Y$ , X, Y= C, N, or O bond length are  $\sim 1.2 \text{ \AA}$

## Representation of Molecules

- Show only electrons in outer (valence) shell
- Non-bonding electrons may not be shown
- Use element symbols, but carbon can be represented by point of angle or end of line
- Hydrogens are understood.

ex)  $C_3H_6$  (propene)

- ring strain can alter normal bond angles

- Hydrogens on atoms that are not carbon are shown

ex)

STEROID

CHOLESTEROL

### Formal Charge

- Convention to keep track of charges
- $\sum$  (sum of) of formal charges = charge on molecule

### Rules

- Add number of protons in nucleus
- Subtract number of inner shell electrons
- Subtract number of unshared electrons
- Subtract  $\frac{1}{2}$  of the number of shared outer shell electrons

### Formal charge on N calculation

Nitrate

$$\begin{aligned}
 &+7 \text{ protons in nucleus} \\
 &-2 \text{ (1s electrons)} \\
 &0 \text{ (unshared electrons)} \\
 &(1/2 \times 8) = -4 \text{ (1/2 unshared electrons)} \\
 &\hline
 &+1
 \end{aligned}$$

For Double bonded oxygen:

$$\begin{aligned}
 &+8 \text{ (number of protons)} \\
 &-2 \text{ (1s electrons)} \\
 &-4 \text{ (unshared electrons)} \\
 &\frac{1}{2} \times 4 = -2 \text{ (1/2 of shared electrons)} \\
 &\hline
 &0
 \end{aligned}$$

For Single bonded oxygen (both):

$$\begin{aligned}
 &+8 \text{ (number of protons)} \\
 &-2 \text{ (1s electrons)} \\
 &-6 \text{ (unshared electrons)} \\
 &\frac{1}{2} \times 2 = -1 \text{ (1/2 of shared electrons)} \\
 &\hline
 &-1
 \end{aligned}$$

Overall Charge is -1

Formal charge on C:

ex)

$$\begin{array}{r}
 +6 \text{ (protons in nucleus)} \\
 -2 \text{ (1s electrons)} \\
 -1 \text{ (unshared electrons)} \\
 (1/2 \times 6) = \underline{-3} \text{ (1/2 unshared electrons)} \\
 0
 \end{array}$$

This species is called methyl radical

Formal charge on C:

ex)

$$\begin{array}{r}
 +6 \\
 -2 \text{ (1s electrons)} \\
 -2 \text{ (unshared electrons)} \\
 (1/2 \times 6) = \underline{-3} \text{ (1/2 unshared electrons)} \\
 -1
 \end{array}$$

This species is called methyl anion and could be written as:
