Polymerisation

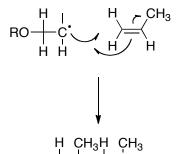

Eg. 1

Eg. 2

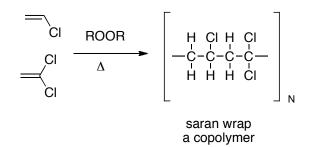

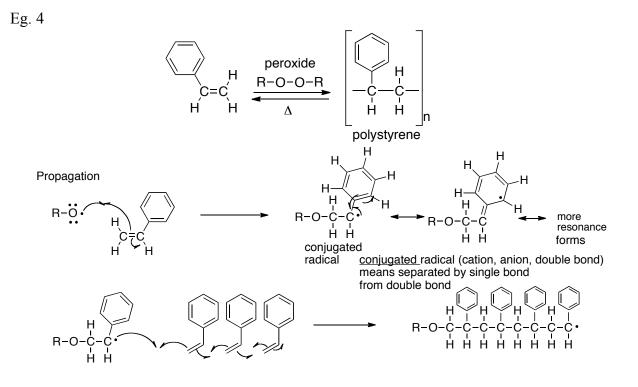

RO-Ċ-Ċ-Ċ-Ċ

termination

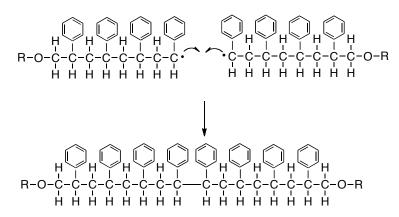

propagation

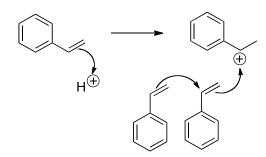

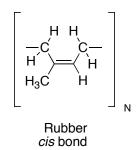

Termination

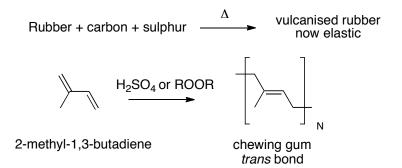

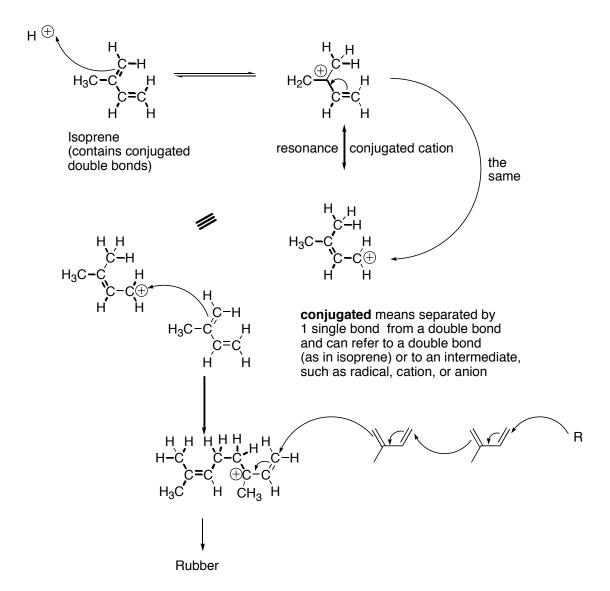

Or cationic acid catalysed mechanism:

Another example:

Reactions of Alkynes

Reactions of alkynes

- 1. Addition (analogous to alkenes)
- 2. At terminal carbon bearing H

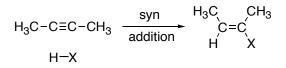

Addition

Halogenation

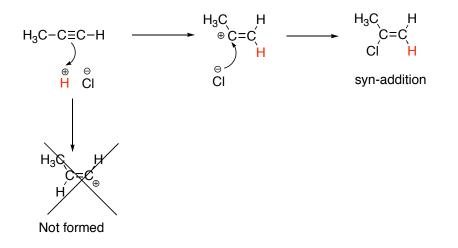

Eg.

$$H_{3}C-C\equiv C-CH_{3} \xrightarrow{Br_{2}} C=C \xrightarrow{Br_{1}} C=C \xrightarrow{Br_{2}} C=C \xrightarrow{Br_{2}} H_{3}C-C-C+CH_{3}$$

HX Addition (syn)

Eg. Propyne (follows markovnikov's rule)

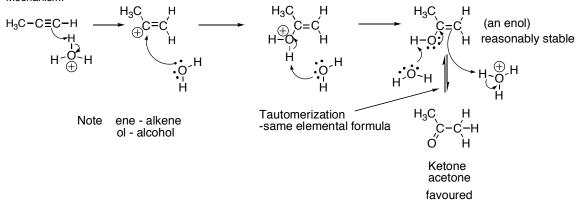

Addition of water (requires acid)

Remember

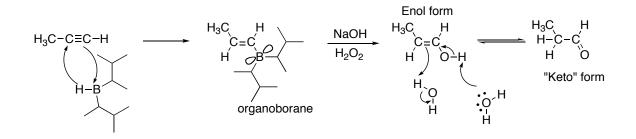

$$H_2O + H_2SO_4 \longrightarrow H_3O^{\oplus} + HSO_4^{\ominus}$$

Mechanism:

Tautomers (eg. keto/enol) are rapidly equilibrating structural isomers. The process is called **tautomerisation**.

Anti-Markovnikov Water Addn - Hydroboration-Oxidation

Two possibilities for reaction of organoboranes:

water and acid to add H and give alkene or NaOH and H₂O₂ to give enol tautomer that converts (equilibrium) primarilty to keto tautomer (aldehyde shown below)

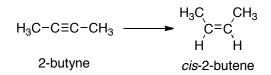

$$H_{3}C-C\equiv C-H \xrightarrow{1) R_{2}BH} H_{3}C-C\equiv C-H \xrightarrow{1) R_{2}BH} H_{0}OH$$

$$HOOH HOOH HOOH$$

$$H_{2}OH = H_{2}OH^{+}, H_{2}OH^{-}$$

$$H_{3}C = CH_{2}$$

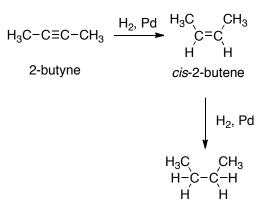

Hydrogenation

1. HBR₂ then $H^+ + H_2O$

OR

2. H₂ and catalyst. However, need a less reactive catalyst.

Lindlar's catalyst

Pd, BaSO₄ (or CaCO₃ is often used in place of BaSO₄), and quinoline (see below):
