CHEM 261 Notes October 10, 2023

#### Recall:

#### Stability of radicals:

- Stability increases with alkyl substitution
- Alkyl groups are polarizable and donate electrons to electron deficient sites better than hydrogens (this is called **inductive effect** and occurs through sigma bonds)

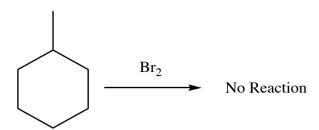

#### Or it can be summarized from least to most stable radicals:

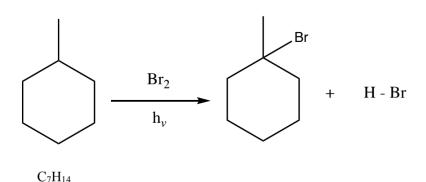

### Halogenation of alkanes:

- requires light or heat to cause a reaction between the starting material and halogen.

#### **Example:**

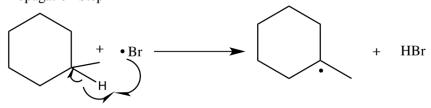

- requires light or heat to cause a reaction between the starting material and halogen.

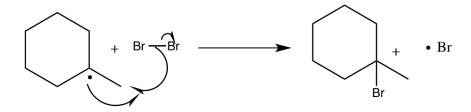

### Initiation Step:

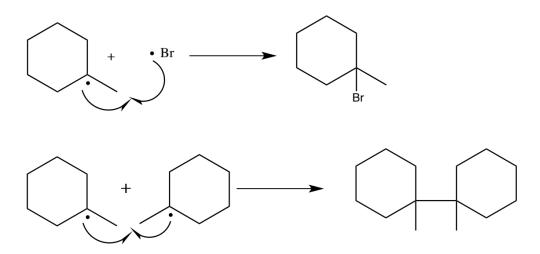

# Propagation Step 1

# Propagation Step 2

Termination Step: Radicals Recombine
-Very minor component of the reaction

Two alkyl radicals combining is highly unlikely because the chances of them finding one another is very low (they are low in concentration) – above also very crowded (steric effect)

$$Br \cdot + Br$$
  $Br_2$ 

#### **Hammond Postulate**

More reactive, less selective

Less reactive, more selective

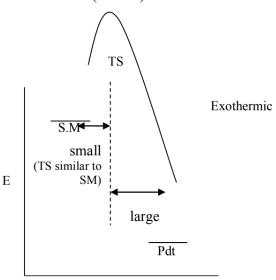

**Exothermic** T.S. (transition state) resembles S.M. (starting material) Less selective reaction because of a small difference in Ea

### Endothermic T.S. resembles product

More selective because of a larger difference in Ea

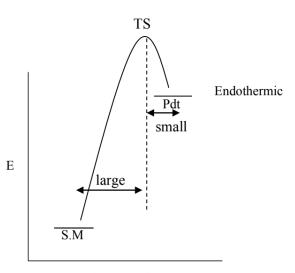

### **Energy Diagrams for Halogenation Reactions**

*Fluorination* ( $\Delta H < 0$ )

Rxn coordinate

*Bromination* ( $\Delta H > 0$ )

Rxn coordinate

E = energy TS = transition state

SM = starting material

Br<sub>2</sub> is less reactive, more selective, endothermic

F<sub>2</sub> is more reactive, less selective, exothermic

$$\frac{\mathsf{Br}_2}{\mathsf{hv}} \left[ \begin{array}{c} \\ \\ \end{array} \right] \xrightarrow{\mathsf{Br}} \left[ \begin{array}{c} \\ \\ \end{array} \right]$$

### **Reactivity and Selectivity (Hammond Postulate)**

e.g. Halogenation of 2-methylbutane

#### I<sub>2</sub> does not react as above

More exothermic, transition state resembles starting materials More endothermic, transition state resembles the product

 $R-H + X_2 \rightarrow R-X + XH$ 

Reactivity:  $F_2 > Cl_2 > Br_2 >> l_2$  (unreactive)

Selectivity: more reactive → less selective (mixture of products)

Less reactive → more selective (single products)

Hammond's postulate:

Chlorination  $\rightarrow$  RDS is exothermic  $\rightarrow$  early TS  $\rightarrow$  small  $\Delta$ Ea Bromination  $\rightarrow$  RDS is endothermic  $\rightarrow$  late TS  $\rightarrow$  large  $\Delta$ Ea

### Naming of Alkyl Halides = Haloalkanes

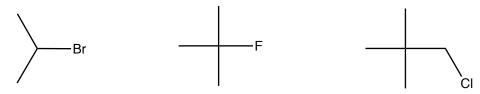

CH<sub>3</sub>Cl CH<sub>2</sub>Cl<sub>2</sub> CHCl<sub>3</sub> CCl<sub>4</sub>

Methyl chloride Chloromethane Dichloromethane CHCl<sub>3</sub> Carbon tetrachloride Tetrachloromethane

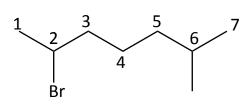

#### **Structure and Nomenclature**

- 1) Find longest chain with largest number of branches
- 2) Number from end so as to give 1st halogen the lowest number
- 3) Name prefix with "halo" (chloro, bromo, iodo, fluoro) OR name alkyl and add halide (chloride, bromide, iodide, fluoride) as the suffix

#### **Examples:**

Isopropyl Bromide tert-Butyl fluoride Neopentyl chloride 2-Bromopropane 2-Fluoro-2-methylpropane 1-Chloro-2,2-dimethylpropane

2-bromo-6-methylheptane

propane

2 -chloro -4-methylhexane

Fluorocyclopropane

5-Butyl-4-iodotetradecane

2-chloro-5-methylhexane

Note: Tert-Butyl = t-Butyl = tertiary Butyl

# **Applications of Haloalkanes**

1.) Halothane (anesthetic)

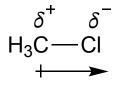

1,1,1-trifluoro-2-bromo-2-chloroethane

2.) Freon = refrigerants/coolants (react with ozone which protects us from strong UV)

3.) 1,1-dibromo-2-chloroethane = male contraceptive (sperm count drops down to zero from 100 million/mL)

### **Physical Properties of Alkyl Halides:**

- Governed primarily by dipole-dipole interactions, more polar than hydrocarbons/alkanes.
- High MP and BP relative to hydrocarbons of similar molecular weight
- Good solvents for organic compounds e.g. methylene chloride (CH<sub>2</sub>Cl<sub>2</sub>) and chloroform (CHCl<sub>3</sub>) are very common.
- If % composition  $\geq$  65% halogen by weight, then more dense than water ( $\rho > 1.0 \text{ g/cm}^3$ )
- Immiscible (insoluble) in H<sub>2</sub>O, which floats on top of the halide

#### <u>Introduction to Stereochemistry and Chirality (terminologies)</u>

*Chiral* object or molecule: has a non-superimposable mirror image *Achiral* object: not chiral, has a superimposable mirror image

Tetrahedral carbon with 4 <u>different</u> groups are said to be **CHIRAL** and are said to contain a **STEREOGENIC (CHIRAL) CENTER** 

Achiral, identical – have a plane of symmetry

Non-superimposable

<u>1850</u> - Louis Pasteur (1822-1895) separated the "right-handed" and "left-handed" forms of tartaric acid crystals (from wine)

<u>1876</u> - J. van't Hoff and Le Bel proposed that differences are due to tetrahedral geometry of carbon

- Kolbe did not receive van't Hoff's idea very well

1901 - J. van't Hoff was the first recipient of the Nobel Prize in Chemistry

*Resolution* – separation of enantiomers

*Enantiomers*: molecules that are stereoisomers and are non-superimposable mirror images of each other. Opposite stereochemistry at every chiral center. Physical properties of enantiomers are the same, as far as they are measured in an achiral environment. A chiral agent of molecule is necessary to distinguish them.

Diastereomers: all stereoisomers that are not enantiomers

#### **Enantiomers**

Same physical properties (i.e., m.p, b.p, etc.)

Bend polarized light differently

Hard to separate

Mirror images

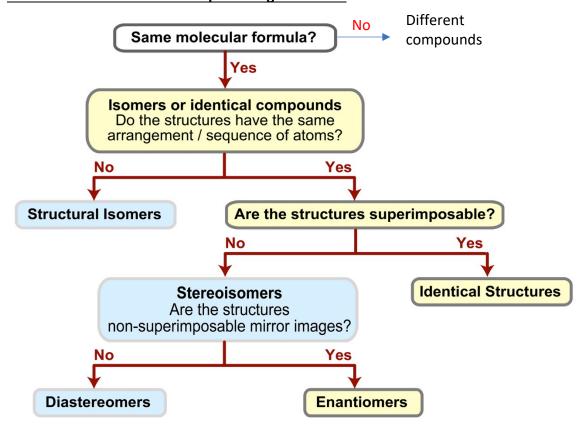

Non-superimposable

#### **Diastereomers**

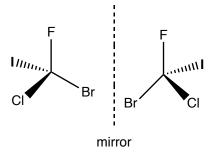

Different chemical properties

Easier to separate Not mirror images Non-superimposable

#### **How to Determine Relationships Among Structures**

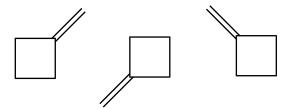

### Example 1:

- Same molecular formula? Yes
- 2) Same arrangement of atoms? Yes
- 3) Superimposable? No
- 4) Non-superimposable mirror images? Yes

#### NON-SUPERIMPOSABLE → Enantiomers

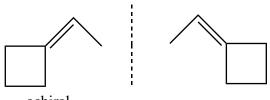

# Example 2:

Identical structures, superimposable, achiral

- Same molecular formula? Yes
- 2. Same arrangement of atoms? Yes
- 3. Superimposable? Yes

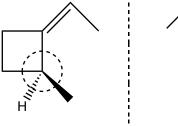

## Example 3:

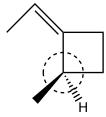

- achiral
- no stereogenic center

Same, identical compound

- Same molecular formula? Yes
- 2. Same arrangement of atoms? Yes
- 3. Superimposable? Yes

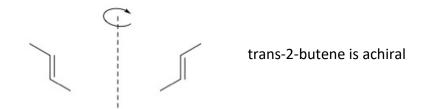

- Same molecular formula? Yes
- 2. Same arrangement of atoms? Yes
- 3. Superimposable? No
- 4. Non-superimposable mirror images? Yes

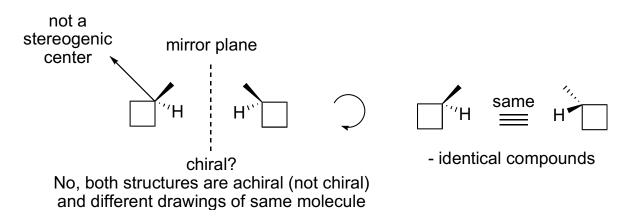

- enantiomers
- dashed circle is stereogenic center carbon atom

# Example 4:

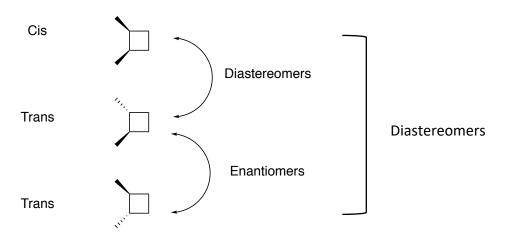

These two mirror images are superimposable as seen by a simple rotation

# **Examples of determining chirality within molecules**

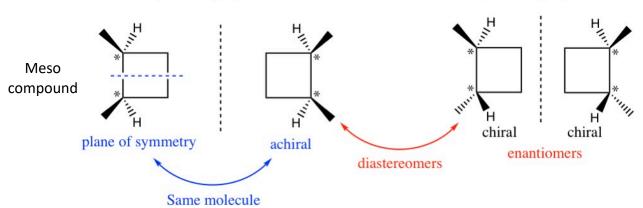

## Example:

Enantiomers have opposite stereochemistry at **every** stereocenter (chiral center)

Diastereomers are all stereoisomers that are not enantiomers cis-1,2-dimethylcyclobutane trans-1,2-dimethylcyclobutane

\* indicates a chiral center

Diastereomers have different physical properties (e.g. mp, bp, etc), and can be separated. Stereogenic centers can exist in a molecule but if there is a plane of symmetry, it renders the whole molecule achiral.

Note: a chiral center (or stereogenic center) exists if <u>4 different groups</u> are attached to the carbon in question

If there is <u>plane of symmetry</u> within a molecule, then the molecule is **achiral** (not chiral)

**Meso compounds** – molecules containing chiral (stereogenic) centers but has a plane of symmetry, therefore they are achiral

#### **Labelling Stereocentres**

#### R/S Nomenclature:

R and S designation of stereoisomers

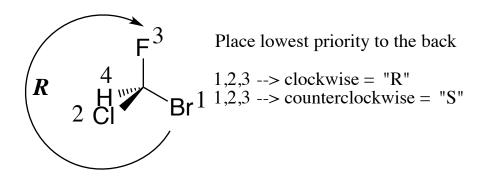

- R = Rectus (right, clockwise)
- S = Sinister (left, counterclockwise)

Labeling a stereogenic center as R or S:

- Identify all stereogenic centers (i.e. 4 different substituents)
- Look at atomic number of atoms attached to the stereogenic center
- Assign priority based on atomic number. If you cannot decide, go to the next set of atoms.

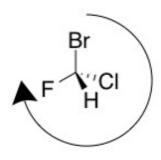

- Number from highest to lowest priority, then with the lowest priority group pointing back, count 1, 2, 3:
  - Clockwise → R configuration
  - o Counterclockwise → S configuration

Each stereogenic center in a molecule is analyzed separately **Example**:

Bromine has the highest atomic number (35), followed by chlorine (17), then fluorine (9), and lastly hydrogen (1).

What if we take mirror image of the molecule above making the lowest priority group now pointing forward?

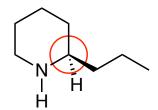

Counting 1, 2, 3 gives clockwise, BUT the smallest group is pointing forward, so the configuration is opposite of what you get if the smallest group is back

In this case, the configuration of the stereogenic center is "**S**"

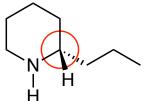

Enantiomers – non-superimposable mirror images of each other

#### Example

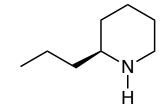

CONIINE, Poison hemlock, potent neurotoxin, killed Socrates

R - enantiomer of coniine Non-toxic

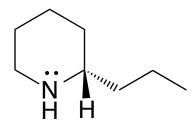

S - enantiomer of coniine - highly toxic - natural

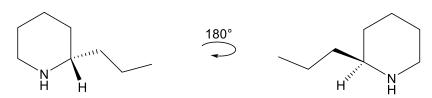

invert EVERY stereocenter

Stereogenic center (chiral centers or asymmetric centers) is circled in red

## **Assigning Configuration:**

1) Move the lowest priority atom to the back (i.e., H)

2) Assign priority to the remaining substituents. Then count 1,2,3.

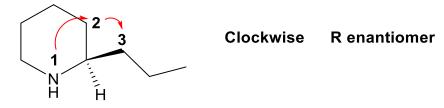

The nitrogen is nominally a stereogenic center since it has 4 different substituents, however it inverts rapidly, and so is not considered stereogenic. (unless all 3 groups are linked/held back by a ring)

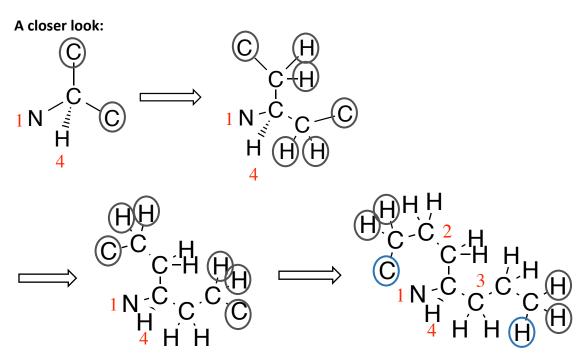

$$CH_2$$
 $N$ 
 $CH$ 
 $CH_2$ 
 $N$ 
 $CH$ 
 $CH_2$ 
 $N$ 
 $CH$ 

To draw the enantiomer of coniine, invert the geometry at the stereocenter

#### Example of determining priority of groups in enantiomer on natural coniine

- We can assign highest priority to the N and lowest to the H, but cannot immediately tell which carbon attached to the stereocenter is of higher/lower priority. When this is the case, we look at the next substituents in the chain.

- We cannot tell at the second attached carbon, so we move on to the third.
- We still cannot tell at the third, so we move on to the fourth.
- At the fourth carbon we can see a difference. The carbon that is part of the propyl group ends in a CH<sub>3</sub> so it is bonded to three H, and the other carbon is bonded to two H and one C. The propyl group gets lower priority (3) and the other group gets higher priority (2).
- Counting 1,2,3  $\rightarrow$  clockwise is R. This is the R enantiomer.
