

Acidity

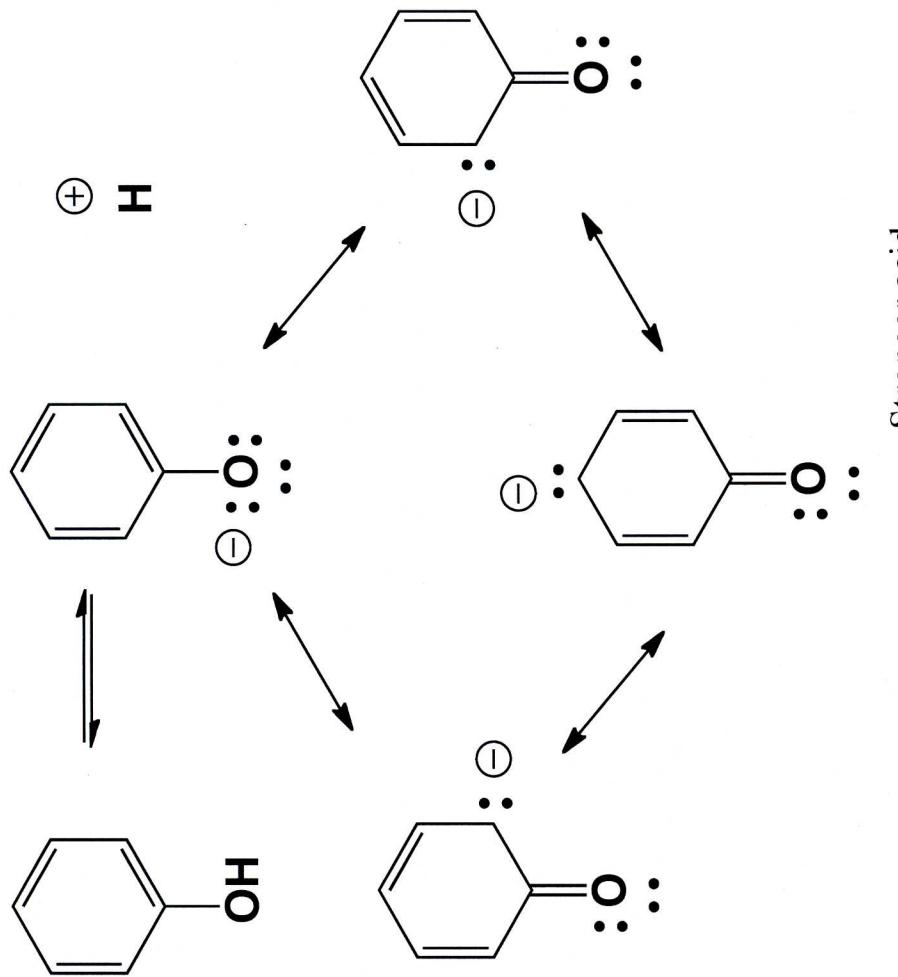

Where does equilibrium lie? Far to right

Stronger base and stronger acid always react quickly
to give weaker acid and weaker base

Phenol has a pK_a value of 10
it is more much acidic (about 6 orders of magnitude) than water (pK_a 15.7)
and methanol (pK_a 16) since it has lower pK_a value)

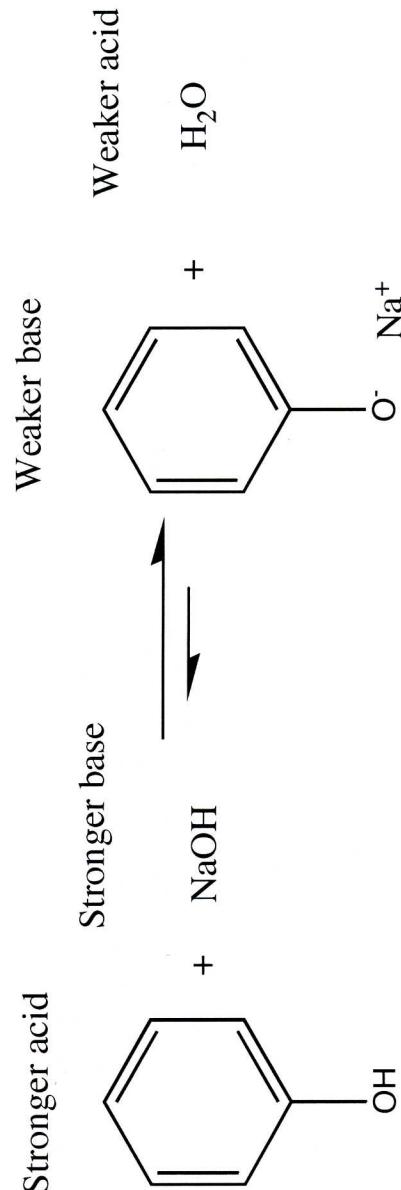

Acidity

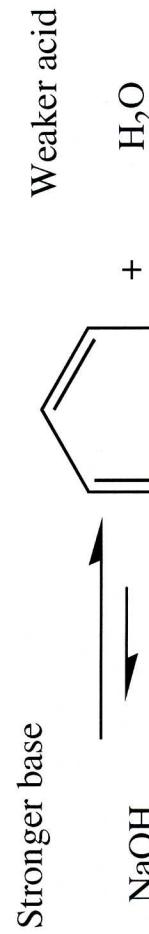

The phenoxide anion is stabilized through resonance

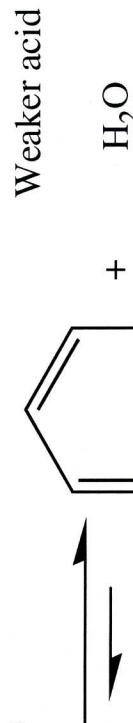

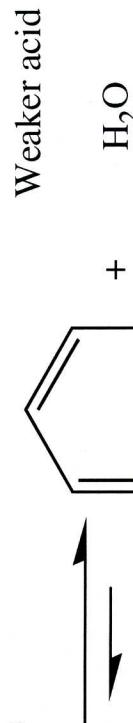

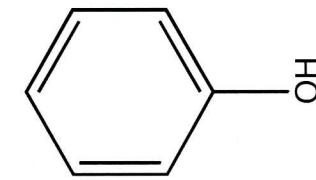

It has 4 resonance forms
that delocalize negative charge

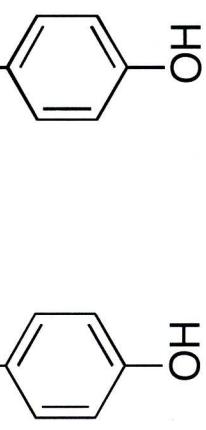

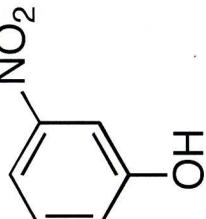

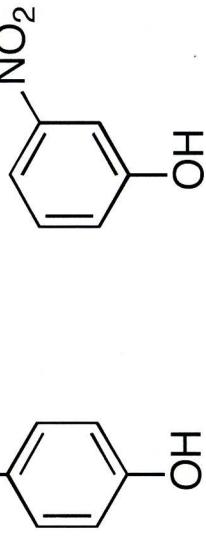

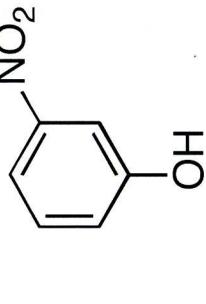

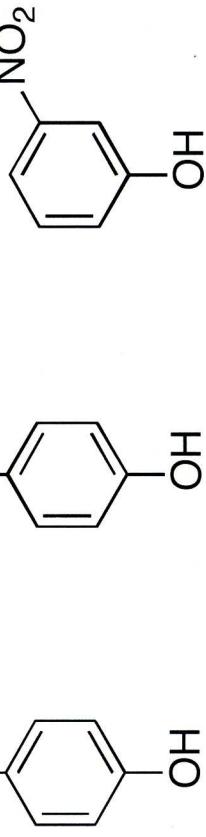

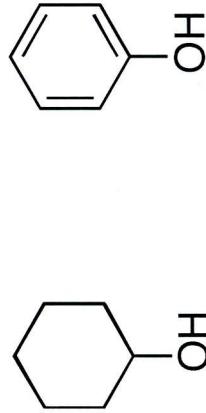

Weaker base

Stronger acid

Acidity

2,4,6-trinitrophenoxy
 $pK_a = 0.5$

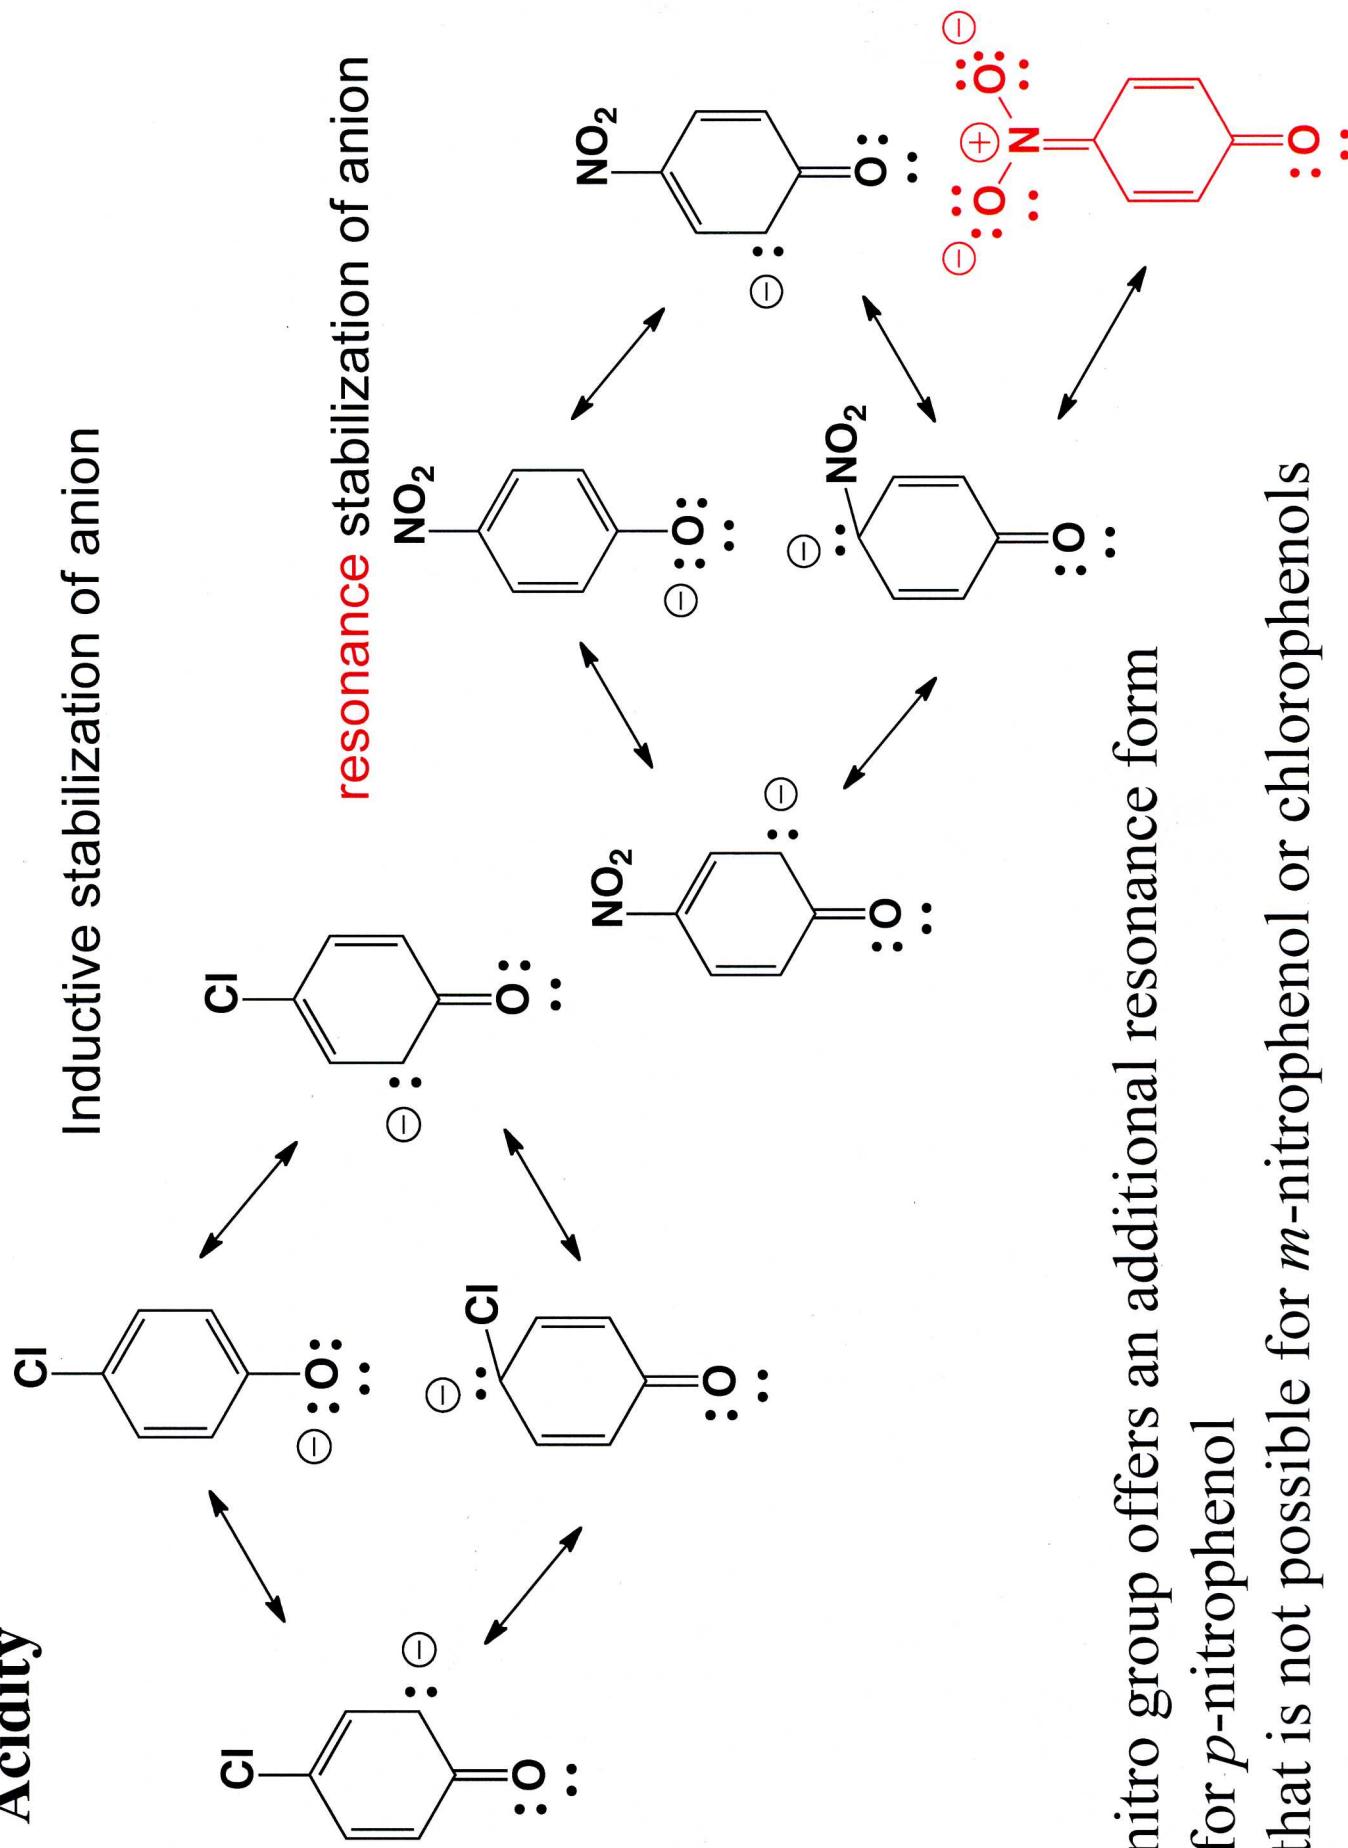

picric acid
 $pK_a = 0.5$

pK_a values show phenol is 10^8 more acidic than cyclohexanol

What is the influence of substituents? inductive & resonance

Acidity

Inductive stabilization of anion

nitro group offers an additional resonance form
for *p*-nitrophenol
that is not possible for *m*-nitrophenol or chlorophenols

Ethers

120

R-O-R', where R and R' can be the same or different, but cannot be carbonyl (C=O)

diethyl ether

Nomenclature:

name the two organic groups and add ether

dimethyl ether

ethoxy

ethyl methyl ether

or ether part is considered to be an alkoxy substituent.

alkene

(*Z*)-3-methoxyhept-3-en-1-ol
(*Z*)-3-methoxy-3-hepten-1-ol

Ethers: Properties

Intermediate polarity - usually have dipoles & can accept Hydrogen bonds

Not miscible with water - very slight solubility

Good solvents for many organic compounds

Less dense than water $\rho < 1.0$ - float on water

Usually chemically unreactive - inert to base - can react with very strong acid

alkene phenol
be able to identify different functional groups

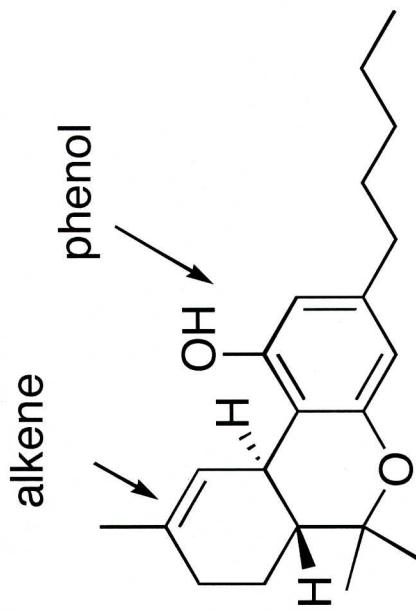

be able to identify stereogenic centres

be able to determine molecular formula

be able to determine reactions discussed in class

e.g. reaction with Br_2 or Br_2 and light

Tetrahydrocannabinol
(THC)

Stereochemistry Review

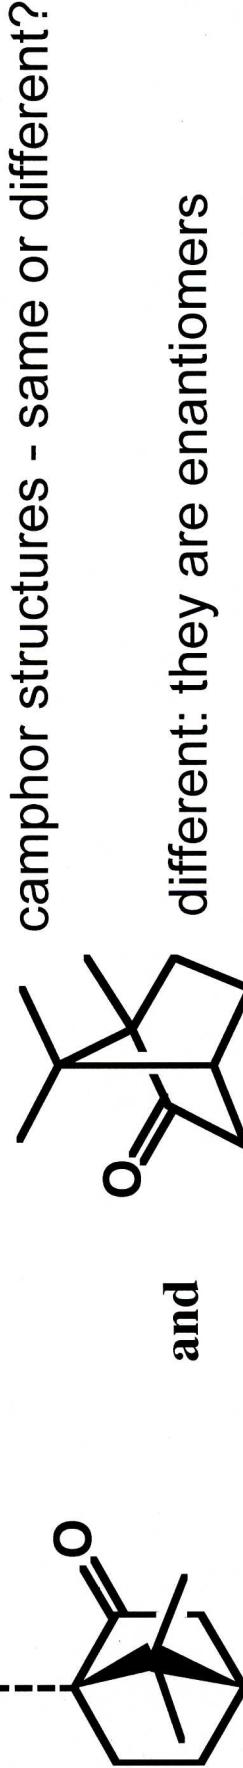

122
Stereochemistry is refers to the three dimensional arrangement of atoms in space

Stereoisomers are different compounds (different physical properties) that have the same connectivity but a different 3D arrangement of atoms

Conformers are **different shapes** of the **same compound**
obtained by rotation around single bonds - usually rapid at room temp
15-20 kcal/mole available at room temp

Resonance Forms are **different pictures** of the **same compound**
obtained by movement of electrons keeping atom positions same

Molecules are 3 dimensional objects - we depict in 2 dimensions

Stereochemistry Review

123

A chiral molecule (or object) is one that has a non-superposable mirror image
achiral molecule has mirror images that are superimposable
if there is a plane of symmetry within molecule is achiral

Stereoisomers that are non-superposable mirror image of each other are **enantiomers**.

All other stereoisomers (which are not mirror images) are called **diastereomers**
